

What is Network

Computer Network is the combination of two or more computers connected with each other to share their resources, establish communication and exchange data electronically based on some pre-agreed rules and protocols.

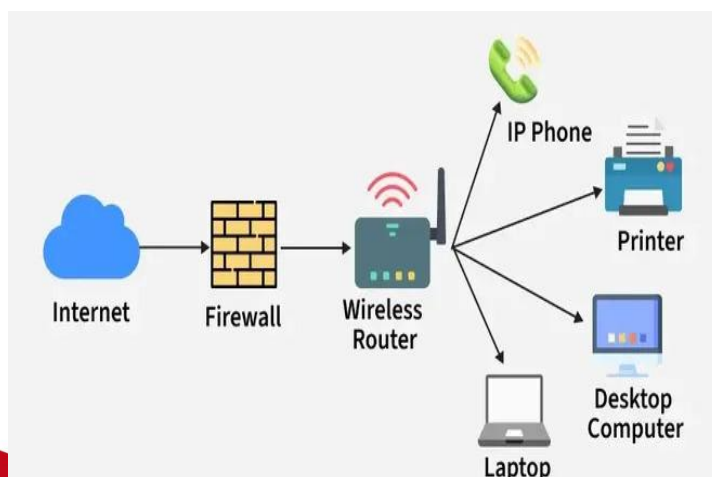

Hosts : The end devices or computers are also known as hosts.

A computer network consists of of networking devices as examples : switches, hubs, routers etc, computer hosts, wired media (copper or fiber cables), wireless media, connectors and software protocols. Multiple computers are connected with each other through

different configurations (physical and logical) known as network topologies. Those computers can be connected through wired or wireless media with the help of media connectors.

This entire hardware configuration is governed by the communication protocols that control the communication rules and patterns in a network. There are many communication topologies, protocols and network types commonly used in computer networks.
